

# THE IMPACT OF SPERM DNA FRAGMENTATION ON ICSI OUTCOMES DEPENDS ON OOCYTE QUALITY

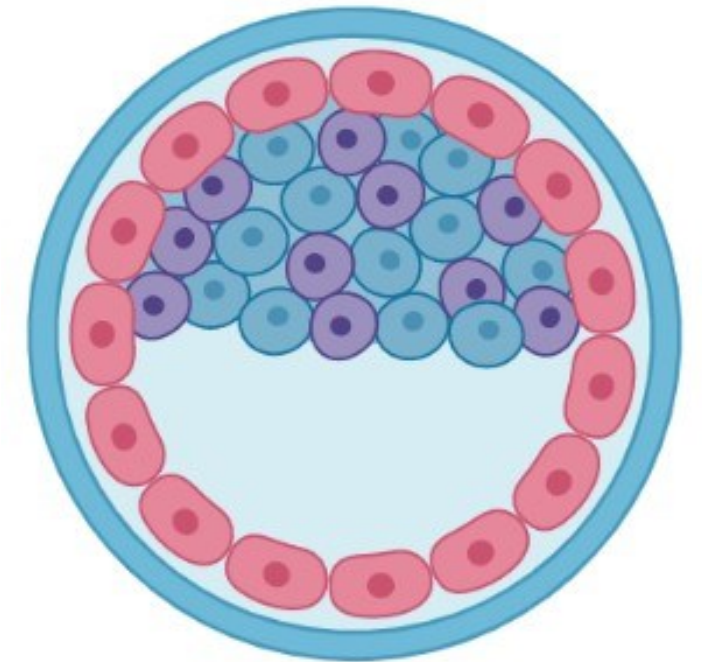

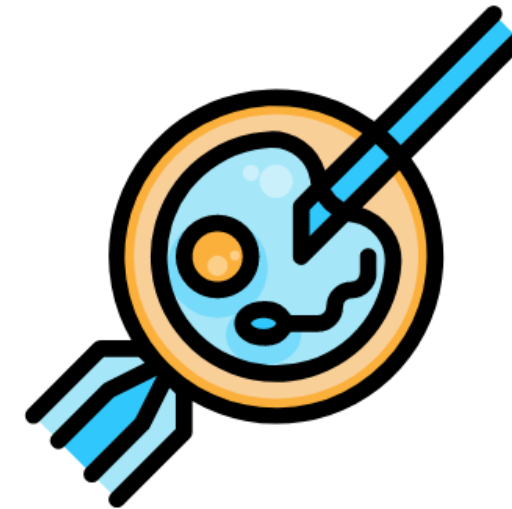

Daniela Paes de Almeida Ferreira Braga, Amanda Setti, Patrícia Guilherme, Rodrigo Rosa Provenza, Assumpto Iaconelli Jr., Edson Borges Jr.

# INTRODUCTION

Parenthood may be achieved by assisted repro

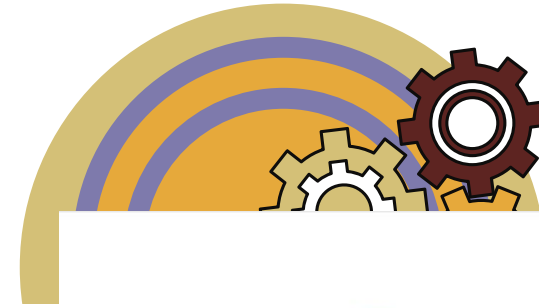

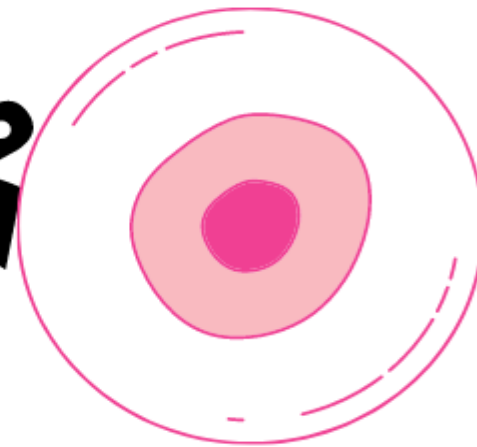

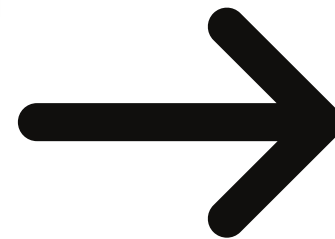

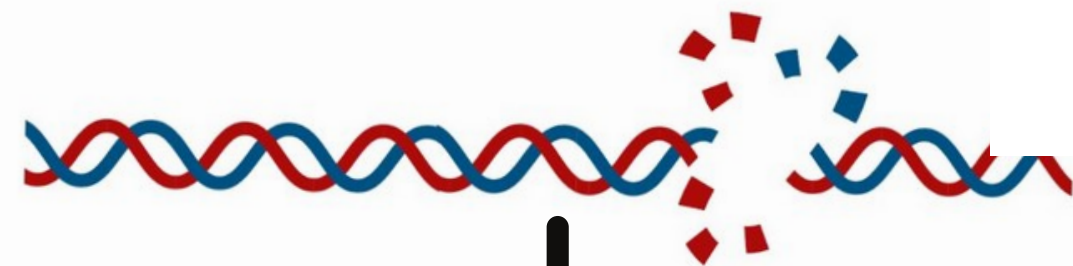

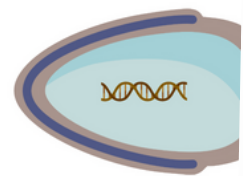

Risk of transmission or induction of genetic and epigenetic conditions cannot be ignored

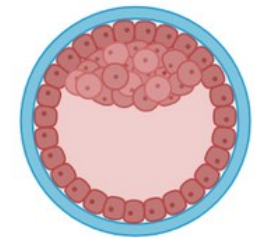

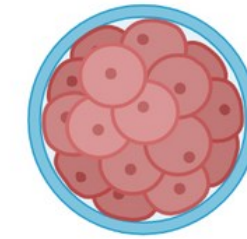

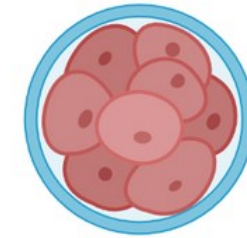

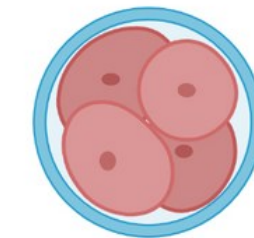

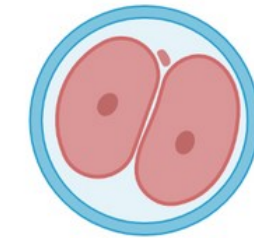

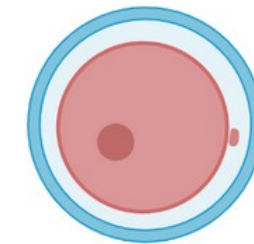

Sperm DNA damage, which is not amended by ICSI, compromises the embryo development

# INTRODUCTION

Sperm repair  
machinery is poor

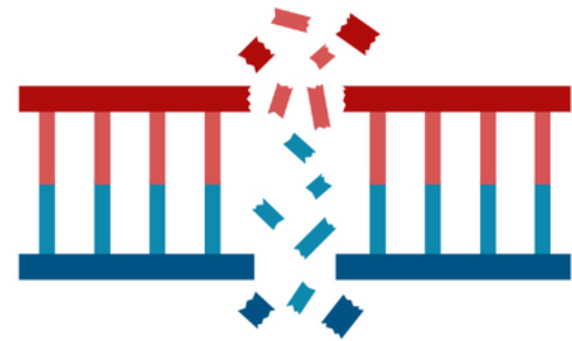

The oocyte is  
responsible for

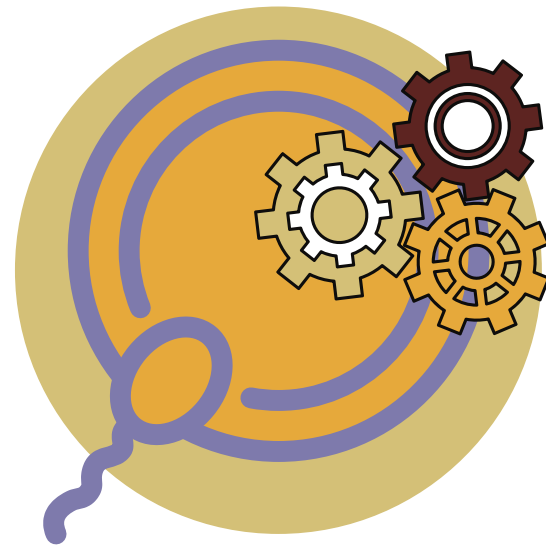

Espermatozoides com dano de DNA podem fertilizar óvulos e levar ao desenvolvimento embrionário graças à habilidade dos óvulos de reparar os danos no DNA

# INTRODUCTION

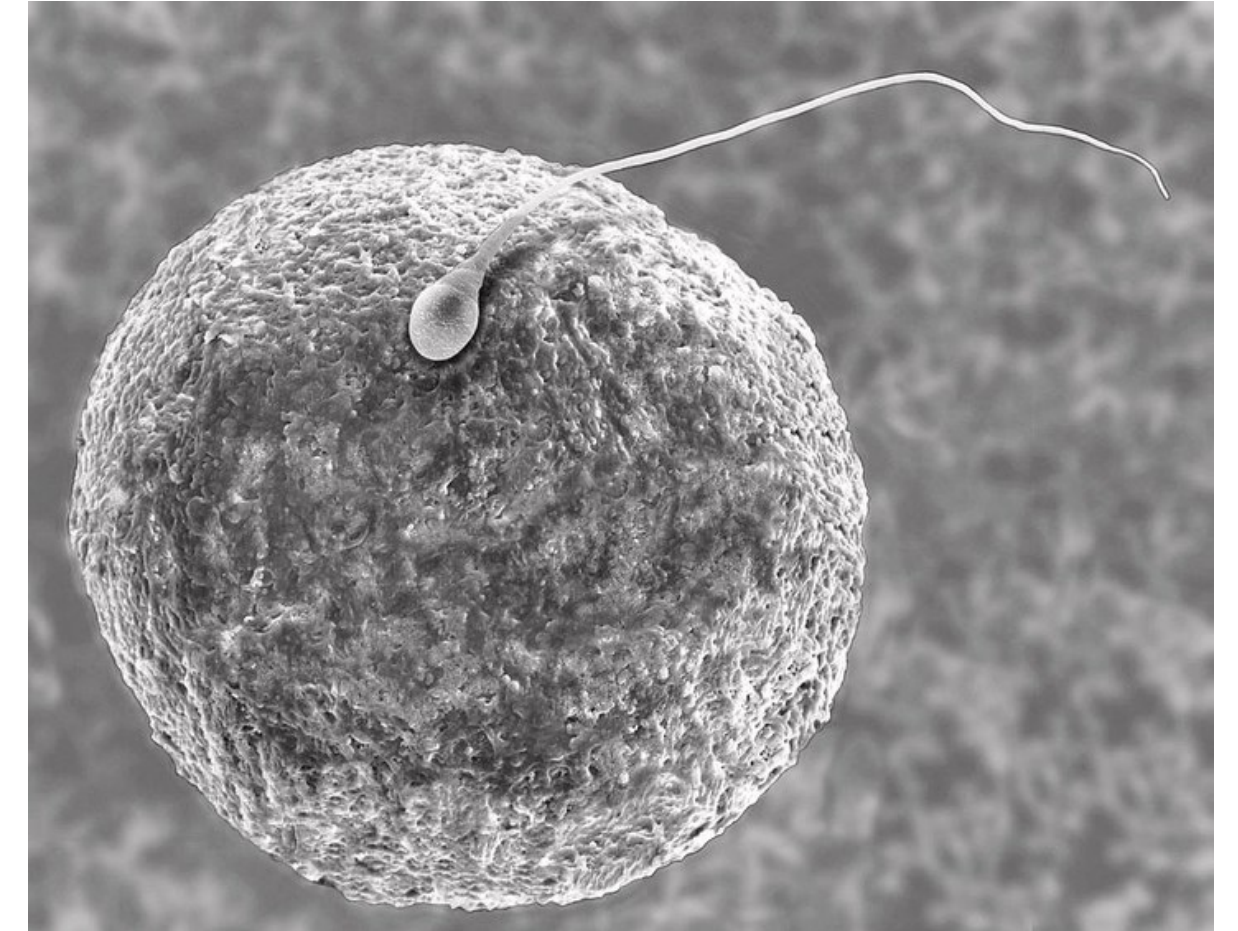

Nature or degree  
of DNA damage

Defects in the oocyte  
repair machinery

Oocyte quality can  
condition the negative  
impacts of SDF on  
pregnancy

**Fertility  
and Sterility®**

Older oocytes, when injected with sperm derived from samples with high SDF index, develop into embryos of poor quality

# INTRODUCTION

Considering the vital  
role played by the  
oocyte in the  
developmental  
process

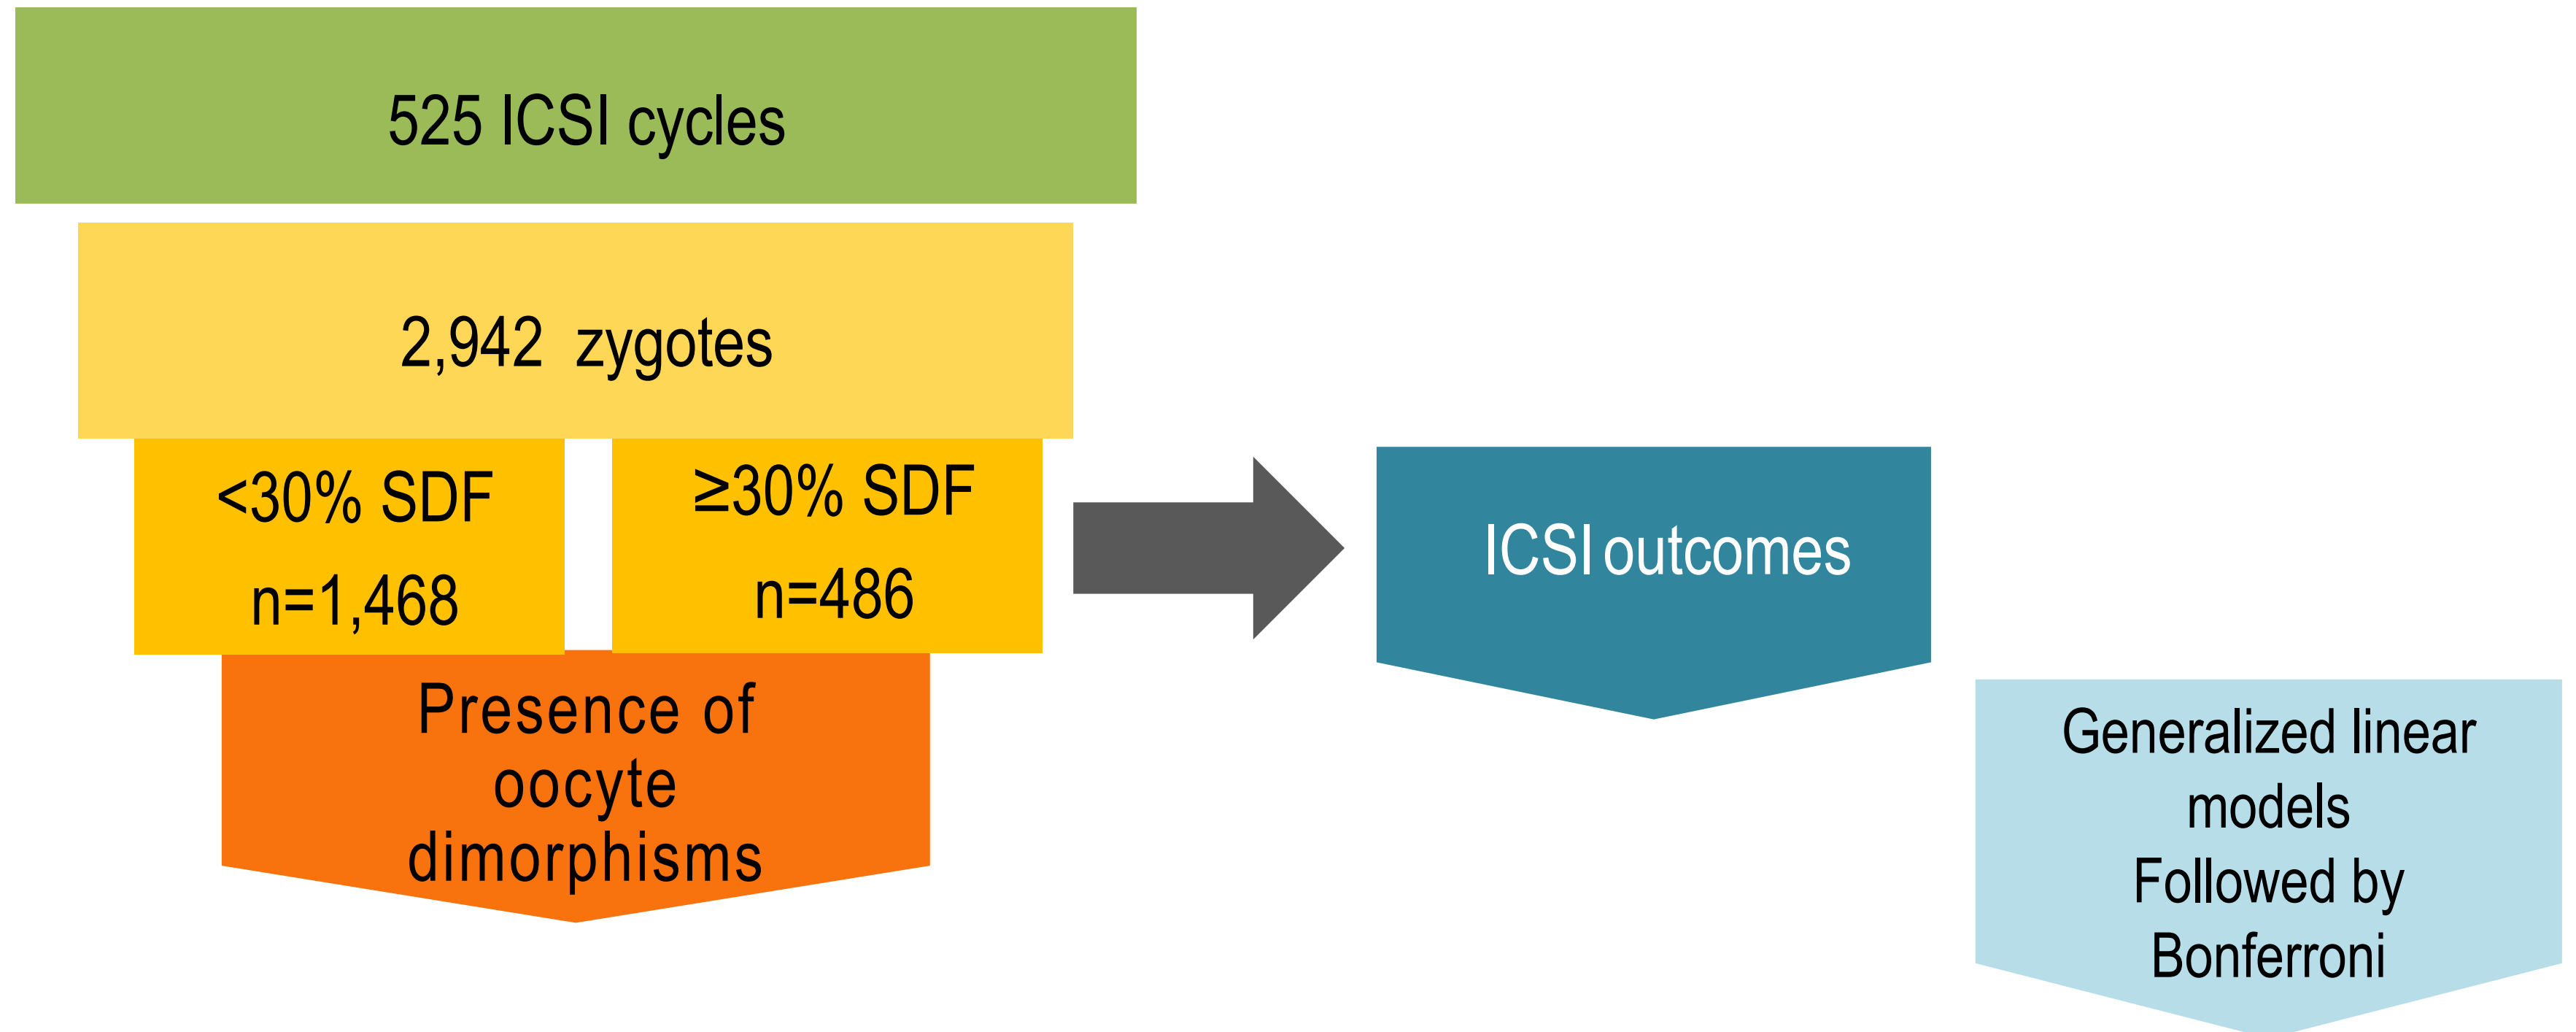

## Hypothesis

Oocyte quality, as indicated by  
oocyte morphology, may influence  
the machinery responsible for DNA  
repair.

# OBJECTIVE

The goal of the present study was to investigate whether the impact of SDF on ICSI outcomes depends on the presence of oocyte dimorphisms

# MATERIAL AND METHODS

# MATERIAL AND METHODS

Pituitary blockage with GnRH antagonist and COS with FSH

Incubation, denudation and nuclear maturation evaluation

Oocytes evaluated for morphology and ICSI performed according with Palermo et al (1992)

Embryo culture until day 5 (one or two blastocysts transferred)

# MATERIAL AND METHODS

## Intracytoplasmic oocyte dimorphisms

Centrally located  
cytoplasmic  
granulation

Vacuoles in the  
ooplasm

Dark cytoplasm

Smooth endoplasmic  
reticulum clusters

# MATERIAL AND METHODS

## Extracytoplasmic oocyte dimorphisms

Large PVS

Zona pellucida  
abnormalities

PVS granularity

Fragmented  
polar body

# MATERIAL AND METHODS

## Other oocyte dimorphisms

Shape abnormalities

Resistant membranes

Non-resistant  
membranes

# MATERIAL AND METHODS

Sperm preparation: 2-layered density gradient centrifugation technique

SDF was measured by using a sperm chromatin dispersion (SCD) test

RESULTS

A significant increase in the fertilization rate and high-quality embryo rate was noted for cycles with <30% SDF, when compared with cycles with ≥30% SDF, regardless of the presence of intracytoplasmic oocyte dimorphisms

# RESULTS

The association of oocyte dimorphism and a high SDF index resulted in the lowest fertilization and/or high-quality embryo rates

RESULTS

A decrease in implantation and pregnancy rates were noted for cycles with ≥30% SDF, when compared with cycles with <30% SDF, regardless of the presence of intracytoplasmic dimorphisms

RESULTS

Significant decrease in implantation and pregnancy rates for cycles with ≥30% SDF, when compared with cycles with <30% SDF, regardless of the presence of extracytoplasmic dimorphisms

RESULTS

The association of a higher SDF index with the presence of oocyte dimorphisms impacted the clinical results for oocytes presenting large PVS, PVS granularity and fragmented PB

# CONCLUSION

The association of low oocyte quality and high SDF indexes may compromise the clinical outcomes specially the miscarriage rate.

# WIDER IMPLICATIONS OF THE FINDINGS

The findings presented here are particularly important for informing patients about the crucial role of both male and female factors when facing ART cycles.

The negative impacts of a high degree of DNA fragmentation on clinical outcomes can be overcome by using high-quality oocytes.

Our evidence supports the hypothesis that defective oocytes lose their ability to cope with SDF and avoid pregnancy loss due to DNA damage in sperm.

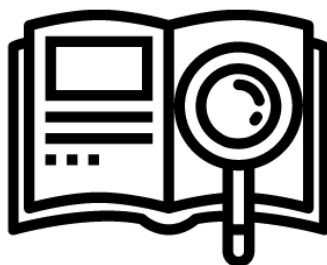

As oocyte defects usually cannot be modified, the in vivo improvement of spermatozoa before ART should be stimulated.
